# Unix/IP Preparation Course May 23, 2010

### Exercises: Permissions

#### REFERENCE

Reference: Shah, Steve, "*Linux Administration: A Beginner's Guide*", 2nd. ed., Osborne press, New York, NY.

If you look at files in a directory using "ls -al" you will see the permissions for each file and directories. Here is an example:

drwxrwxr-x	3 hervey	hervey	4096 Feb 25 09:49 directory
-rwxrr	12 hervey	hervey	4096 Feb 16 05:02 file

The left column is important. You can view it like this:

Туре	User	Group	Other	Links	owner	group	size	date	hour	name
d	rwx	rwx	r-x	3	hervey	hervey	4096	Feb 25	09 <b>:</b> 49	directory
-	rwx	r	r	12	hervey	hervey	4096	Feb 16	05 <b>:</b> 02	file

So, the directory has r (read), w (write), x (execute) access for the User and Group. For Other it has r (read) and x (execute) access. The file has read/write/execute access for User and read only access for everyone else (Group and Other).

To change permissions you use the "chmod" command. chmod uses a base eight (octal) system to configure permissions. Or, you can use an alternate form to specify permissions by column (User/Group/Other) at a time.

Permissions have values like this:

Letter	Permission	Value
R W X	read write execute none	4 2 1 0

Thus you can give permissions to a file using the sum of the values for each permission you wish to give for each column. Here is an example:

Letter Permission Value

	none	0
r	read only	4
rw-	read and write	6
rwx	read, write, and execute	7
r-x	read and execute	5
x	execute	1

This is just one column. Thus, to give all the combinations you have a table like this:

Permissions	Numeric equivalent	Description
-rw	600	User has read & execute permission.
-rw-rr	644	User has read & execute. Group and Other have read permission.
-rw-rw-rw-	666	Everyone (User, Group, Other) have read & write permission (dangerous?)
-rwx	700	User has read, write, & execute permission.
-rwxr-xr-x	755	User has read, write, & execute permission. Rest of the world (Other) has read & execute permission (typical for web pages or 644).
-rwxrwxrwx	777	Everyone has full access (read, write, execute).
-rwxxx	711	User has read, write, execute permission. Group and world have execute permission.
drwx	700	User only has access to this directory. Directories require execute permission to access.
drwxr-xr-x	755	User has full access to directory. Everyone else can see the directory.
drwxxx	711	Everyone can list files in the directory, but Group and Other need to know a filename to do this.

Note: "Other" is often referred to as "World".

## **1.) CHANGING FILE PERMISSIONS**

If you are logged in as the *root* user please do the following:

# exit

To become a normal user, like *afnog*. Your prompt should change to include a "\$" sign.

\$

Once logged in we'll create a file and set permissions on it in various ways.

\$ cd
\$ echo "test file" > working.txt
\$ chmod 444 working.txt

In spite of the fact that the file does not have write permission for the owner, the owner can still change the file's permissions so that they can make it possible to write to it. Do you find this to be strange?

\$ chmod 744 working.txt

Or, you can do this by using this form of chmod:

\$ chmod u+w working.txt

To remove the read permission for the User on a file you would do

\$ chmod u-r working.txt

Or, you can do something like:

\$ chmod 344 working.txt

You probably noticed that you can use the "-" (minus) sign to remove permissions from a file. Try reading your file:

\$ cat working.txt

What happened? Uh oh! You can't read your file. Please make the file readable by you:

\$ chmod ??? working.txt

Ask your instructor for help if you don't know what to put in for "???". Or, look at your reference at the start of these exercises to figure this out.

## 2. PROGRAM EXECUTION, PRIVILEGES & SUDO

As a general user you can see that there is a file called "master.passwd":

\$ ls /etc/master.passwd

But, you *cannot* see its contents:

\$ less /etc/master.passwd

As a general user, however, you can see the /etc/master.passwd file if you do the following:

\$ sudo less /etc/master.passwd

What is sudo? Read about it:

\$ man sudo

# **3. CREATE A NEW GROUP**

\$ sudo pw groupadd team1

Prove that it really exists:

\$ sudo grep team1 /etc/group

Now let's place our *afnog* user in this new group:

\$ groups

You can see that *afnog* is a member of the *wheel* group.

\$ sudo pw usermod afnog -G team1

You won't be able to use your new group until you have logged in and out from your account, or have simulated this process by doing this:

\$ su - afnog

Now try typing:

\$ groups

Using groups like this can be useful for working in teams on a project, giving access to web directories, etc.

## 4. GIVE GROUP ACCESS TO A FILE

Do the following:

\$ cd
\$ echo "This is our group test file" > group.txt
\$ chgrp team1 group.txt

What permissions does the file have now?

\$ ls -l group.txt

You should see something like:

-rw-r--r-- 1 afnog team1 10B May 23 10:14 group.txt

How would you give members of the group team1 read/write access to this file? Before you look below try solving this on your own.

We'll use the numeric chmod functionality.

\$ chmod 664 group.txt

Alternatively you could have typed:

\$ chmod g+w group.txt

Look at the file's permissions:

\$ ls -l group.txt

You should see something like:

-rw-rw-r-- 1 sysadmin team1 19 Jul 24 10:14 group.txt

## **5. MAKE A FILE EXECUTABLE**

Do this exercise as the *afnog* user.

\$ cd
\$ touch hello
\$ vi hello

Now add a single line to the file that reads:

echo 'Hello, world!'

Do this by pressing the "i" key to go in to insert mode in vi. Type in the text, then press the ESCape key, and then press ":wq" to write and quit from the file.

At this point let's try to run this file:

\$ ./hello

You'll probably see something like:

bash: ./hello: Permission denied

This implies that the file is not executable. We need to set the file's permission to be executable by our *afnog* user. How would you do this?

\$ chmod 755 hello

would work. Now try running the file:

\$ ./hello

You should see

Hello, world!

on your screen. You've just written your first script!

Now set your hello file to be readable, but not executable by the *afnog* user and executable by the Group and by Other. Can you figure out how to do this on your own?

What happens if you now type?

\$ ./hello

Why does this happen? If you execute the file as a different user it will still work! Does this seem odd? (**Hint**: think "left to right")

## CONCLUSION

## What's the "./" about?

In our example above when you typed "hello" the file "hello" is in your home directory. Your home directory *is not* in your default path as configured for the bash shell. Thus, bash will not find the hello file, even though it's in the same directory where you are typing the command. By using "./" before the filename we tell bash to explicitly look in the same directory for the file to execute.

## What about setuid, setgid and sticky bits?

Have a look at: http://www.onlamp.com/pub/a/bsd/2000/09/13/FreeBSD Basics.html
